ABSTRACT: Construction of *in vitro* vascular models is of great significance to various biomedical research, such as pharmacokinetics and hemodynamics, and thus is an important direction in the tissue engineering field. In this work, a standing surface acoustic wave field was constructed to spatially arrange suspended endothelial cells into a designated acoustofluidic pattern. The cell patterning was maintained after the acoustic field was withdrawn within the solidified hydrogel. Then, interstitial flow was provided to activate vessel tube formation. In this way, a functional vessel network with specific vessel geometry was engineered on-chip. Vascular function, including perfusability and vascular barrier function, was characterized by microbead loading and dextran diffusion, respectively. A computational atomistic simulation model was proposed to illustrate how solutes cross the vascular membrane lipid bilayer. The reported acoustofluidic methodology is capable of facile and reproducible fabrication of the functional vessel network with specific geometry and high resolution. It is promising to facilitate the development of both fundamental research and regenerative therapy.

KEYWORDS: *acoustofluidics, surface acoustic wave, vessel-on-a-chip, biofabrication, vascular barrier function*

■ **INTRODUCTION**

The vascular system is one of the most important circulatory systems in the human body.^{[1](#page-5-0)} Blood vessels are not only necessary pathways for physiological metabolism, material exchange, and nutrient delivery but also important routes for most pharmacokinetic drug delivery.[2,3](#page-6-0) Therefore, *in vitro* reconstruction of functional vascular models has always been one of the key research topics in the field of tissue engineering.^{[4](#page-6-0)}

At present, the self-assembly nature of endothelial cells (ECs) is mostly used for *in vitro* capillary vessel network construction, $5-9$ $5-9$ with inevitable randomness and low reprodu $cibility¹⁰$ In order to match specific different structures and functions of each organ, the blood vessels have significant organ specificity.^{[11](#page-6-0),[12](#page-6-0)} For example, the vascular structure in the hepatic lobule has a hexagonal distribution, 13 13 13 while the vessels in muscle tissue run in parallel lines. 14 In an attempt to control the vessel shape, researchers have been building blood vessels by coating the inner surface of hollow gel channels with ECs[.15](#page-6-0)[−][17](#page-6-0) Nonetheless, limited by the template resolution and difficulty of removing the mold template without destroying the channel, it is difficult to achieve micron-scale blood vessels with slightly complex shapes.^{[18](#page-6-0),[19](#page-6-0)} Multiphoton ablation technology reported by Zheng et al. can generate the hollow gel channels with intricate patterns of a few microns, accurately controlling the shape and size of blood vessels at the same time.[20](#page-6-0)[−][22](#page-6-0) However, the complexity and cost of the laser machine system may limit its widespread adoption. Due to various strengths, such as remote control, biocompatibility, and

noncontact and easy operation, acoustofluidics has gradually developed into a popular biomedical technology^{23,24} and is developed into a popular biomedical technology^{[23](#page-6-0),2} widely used in the fields of disease diagnosis,^{25−[30](#page-6-0)} drug delivery[,31](#page-6-0),[32](#page-6-0) tissue engineering,[33](#page-6-0)−[38](#page-7-0) and biophysical characterization.[39,40](#page-7-0) Here, we report a standing surface acoustic wave (SSAW)-based acoustofluidic methodology as an alternative to engineering vessel-on-a-chip. First, the suspended endothelial cells were acoustically patterned into parallel line topography in the hydrogel matrix. Then, the patterned endothelial cells were activated by the interstitial flow and developed into functional vessel tubes along the previous acoustic patterning geometry. The permeability difference between the monovessel and fibroblast-supported vessel was evaluated, and a computational model was proposed for interpretation. Last, by characterizing the compound response of neurons in the pure matrix and in the vessel-associated matrix, we demonstrated the influence of blood vessels. The reported acoustofluidic vessel engineering demonstrates that, without any physical channel as a guide, the HUVECs can still be assembled into the vessel network with the designated specific geometry. Besides, the cost of the acoustofluidic system is more lab-

Figure 1. Schematics of acoustofluidic engineering functional vessel-on-a-chip. (A) As shown schematically, standing surface acoustic wave is generated on-chip to pattern the cells and promote the desired vessel formation. (B) Flowchart of the acoustofluidic engineering of vessel formation. The suspended cells are patterned into the acoustic pressure node and aligned into a parallel line array. After the acoustic field disappears, the solidified gel can still maintain the original patterning shape of the cells. Due to the nature of adherent growth, some excess vascular cells will grow along the wall of the PDMS chamber, forming transverse vessels perpendicular to the patterned longitudinal vessel tubes, thereby connecting these parallel arrays of vascular tubes. In the end, a functional vessel-on-chip can be formed with the interstitial flow stimulation.

friendly than the photon laser facility. Thus, it is promising to be an alternative method for the facile and high-resolution construction of the *in vitro* vessel model.

■ **MATERIALS AND METHODS**

Acoustofluidic Device Fabrication. The SSAW device was fabricated through a standard lithography and lift-off process.^{[41](#page-7-0)} A 15 *μ*m-thick photoresist layer (AZ512, Kayaku Advanced Materials, Inc.) was spin-coated on a 500 *μ*m-thick, double-sided polished, piezoelectric LiNbO₃ wafer (Precision Micro-Optics, Inc.). Then, the designed interdigital transducers (IDTs) of double metal layers (Cr/ 100 Å, Au/600 Å) with a 125 *μ*m finger width were transferred from the customized plastic mask to the substrate by metal deposition.⁴ The finger pair number of the IDT is 30. The resonant frequency of the obtained SSAW device was measured as around 8.21 MHz. The microfluidic chamber mold was fabricated with soft lithography.^{[43](#page-7-0)} A 150 *μ*m-thick SU8-2150 (Kayaku Advanced Materials, Inc.) photoresist mold was created on a 3 in. silicon wafer. After being peeled off from the mold, the polydimethylsiloxane (PDMS) chambers were plasma-bonded on a 1 mm-thick glass coverslip.^{[44](#page-7-0)} All of the fabrication processes were finished in the Center for Photonics and Nanoelectronics (CPN) at Lehigh University.

Cell Culture, Experimental Setup, and Immune-Fluorescence Staining. Human Umbilical Vein Endothelial Cells (HUVECs) and Normal Human Lung Fibroblasts (NHLFs) were purchased from LONZA. 45 45 45 HUVECs were cultured in an endothelial cell growth medium supplemented with an EGM-2 SingleQuot kit supply and growth factors (EGM-2, LONZA). NHLF were cultured in fibroblast growth basal medium supplemented with FGM-2 BulletKitTM (FGM-2, LONZA).⁴⁶ The generation of excitatory human forebrain neurons was accomplished using overexpression of Neurogenin-2 (NGN2) transcription factor, following the protocol.^{47,48} The neurons were cultured with complete mTeSR1 medium; differentiation to the neuron occurred with the introduction of dox to the culture (N2 supplement + doxycycline and growth factors in DMEM/F12 media), and it was maintained in the culture with a 50× B27 supplement and 2 mM L-glutamine in Neurobasal medium (Thermo Fisher Scientific). All cells were cultured at 37 °C in a humidified 5% $CO₂$ environment.

For the patterning experiment, bovine fibrinogen (CAS-9001-32-5, Sigma) was dissolved in Dulbecco's phosphate buffered saline (DPBS) to 2 mg/mL solution. The cell-laden fibrinogen pregel solution was mixed with 2 U/mL bovine thrombin (CAS-9002-044, Sigma) and injected into the chamber through chamber loading ports.^{[49](#page-7-0)} For the pure HUVEC condition, the cell concentration was 5 million/mL. For the coculture situation, the HUVEC concentration

was retained at 5 million/mL, while the concentration of another cell was 0.2 million/mL. During the cell patterning experiment, a radio frequency signal from a function generator (AFG3102, Tektronix, USA) was amplified by an amplifier (ACS-230-25W, Com-Power, USA) and transferred to the IDT pair. The input voltages on the devices were from 50 Vpp. A coupling water layer was placed between the SSAW device and the PDMS-glass-based microfluidic chamber for acoustic wave conduction.^{[50](#page-7-0),[51](#page-7-0)} The HUVECs were aligned into parallel lines in PDMS channels during 3 min of the acoustic patterning process. Then, the PDMS chambers were relocated into the incubator for gel solidification and further *in vitro* cell culture.[52](#page-7-0)

For immunofluorescence staining of the vessel model, the detailed method can be found in our previous publication.^{[9](#page-6-0)} For the neural cellvessel coculture system, 1.0 mM monosodium glutamate (MSG) (Sigma-Aldrich) was dissolved in EGM medium and loaded into the vessel tube. c-Fos (sc-166940-AF488, Santa Cruz)⁵³ immunostaining was executed 10 min after loading the monosodium glutamate solution. All of the fluorescent images and confocal scanning were acquired with a Nikon C2+ laser scanning confocal microscope in the Health Research Hub Center, Lehigh University. The image processing was conducted with ImageJ software from the National Institutes of Health (USA).

On-Chip Vessel Network Construction and Vascular Permeability Characterization. After the gel curing, a pipet tip containing 50 *μ*L of culture medium was inserted into one of the chamber loading ports to provide interstitial flow and hydrostatics, while an empty pipet tip was inserted into the other chamber loading port for medium collection.^{9,[45](#page-7-0)} The culture media in pipet tips were refreshed every day. The permeability of the vessels was measured with solute diffusion across the vessel wall. 70 kDa FITC conjugated dextran (CAS-60842-46-8, Sigma) was dissolved in the EGM-2 medium to prepare the solution.^{54,55}

Computational Simulation. COMSOL Multiphysics 5.6 was exploited to simulate the defined central area that resulted from the interference of two opposing SAWs. A "Pressure Acoustic, Frequency Domain" is used to analyze the pressure distribution of a one-
dimensional standing acoustic field:^{[56](#page-7-0)−[60](#page-7-0)}

$$
\nabla \left(-\frac{1}{\rho_0} \nabla p \right) = \frac{\omega^2}{\rho_0 c^2}
$$

where ω is the angular frequency, c is the sound speed, ρ_0 is the density, and *p* is the pressure.

In the permeability computational model, the 70 kDa FITCdextran solute is represented as a series of discrete beads uniformly distributed on one side of the simulation domain [\(Figure](#page-3-0) 4A green beads). The Cooke-Deserno three-bead membrane representation

model is implemented to simulate the vascular membrane, which offers an elegant balance between computational simplicity and biological realism.[61](#page-7-0)−[63](#page-7-0) The interaction between these entities is defined by employing the Lennard-Jones potential, allowing for the manifestation of Brownian motion among the beads. The use of the Lennard-Jones potential not only provides a mechanism for interaction between the beads but also models the diffusion of these bead-represented solutes through the membrane. $64,65$ Within this framework, each lipid is depicted as three discrete beads, representing the hydrophilic headgroup (red in [Figure](#page-3-0) 4) and the two hydrophobic tail groups (blue in [Figure](#page-3-0) 4), effectively capturing the amphiphilic nature of lipids. These coarse-grained head and tail beads are interconnected via a finite extensible nonlinear elastic bond, thus capturing the essential amphiphilic character of lipids. Additionally, a harmonic angular potential is employed to maintain the straightened configuration of the lipid molecule. To closely emulate the experimentally observed diffusion rates of membrane permeability, the area per lipid in the membrane was optimized by adjusting the Lennard-Jones parameters. Several basic assumptions are preset to improve computational efficiency and clarity: (1) The lipid bilayer was conceptualized as a seamless, uniform surface, intentionally omitting intricate molecular details to reduce computational complexity. (2) The complexities of lipid headgroups and tails are abstracted into coarse-grained beads, encapsulating essential interaction properties. (3) The behavior and dynamics of the membrane are primarily driven by a balance between curvature elasticity and thermal fluctuations. The membrane representation and the associated parameters were described in our previous publication.^{66,6}

■ **RESULTS AND DISCUSSION**

Acoustofluidic Patterning of the Suspended HUVECs into Acoustic Pressure Nodes. [Figure](#page-1-0) 1 illustrates the methodology workflow of the acoustofluidic vessel-on-a-chip engineering. Once the signal of resonant frequency from the signal generator was amplified and introduced to the acoustofluidic device, two identical but opposite-propagating traveling surface acoustic waves (SAWs) were released from

the IDT pair, and the SSAW field was constructed on the piezoelectric LiNbO₃ wafer surface.^{[68,69](#page-7-0)} Thus, a periodic distribution of pressure nodes and antinodes with minimum and maximum pressure amplitudes was presented, respectively (Figure 2B).[70](#page-7-0)[−][72](#page-7-0) With the conduction of the coupling water layer, the acoustic field was introduced into the chamber.^{[73](#page-8-0)} As a result, the originally randomly distributed cells were relocated to the nearest pressure nodes, thus forming parallel linear arrays.^{[74](#page-8-0)} Here, the half wavelength of the SSAW was designed as 250 *μ*m, and the final patterned cell line spacing was approximately 150 μ m (Figure 2C). Fibrinogen is currently the most suitable hydrogel for culturing vascular tissue *in vitro*, and it was selected as the biological matrix in this experiment.^{[75,76](#page-8-0)} The thrombin concentration was reduced to prolong the time required for the gel solidification until the cells could be fully patterned. In the experiment, it was observed that the fibrinogen gel began to coagulate after being mixed with thrombin for 3 min at room temperature, at which time the cells rarely moved. Thus, after 3 min, the sample was moved into the incubator for full solidification. After 3 min of patterning, the microfluidic chambers were moved into the incubator to fully solidify the gel. In this way, the original cell patterning topography was maintained by the solidified gel after the acoustic field was withdrawn.⁷

Patterned Vessel-on-a-Chip Formation under Interstitial Flow-Assisted *in Vitro* **Cell Culture.** Prior to this project, several papers were published on the construction of vascular models by acoustic cell patterning.⁷⁸⁻⁸⁰ For example, vascular models by acoustic cell patterning.^{[78](#page-8-0)} Kang et al. acoustically patterned endothelial cells in hyaluronic acid to construct vascular tissue for ischemia therapy.[81](#page-8-0) The authors transplanted the *in vitro* vascular tissue into a mouse model. After the vascular tissue was anastomosed with the rat's own blood vessels, the vessel perfusability was verified *in vivo*. Besides, Zhang et al. reported that, for *in vitro* vascular models, the key to making vessel tubes perfusable is to

provide a stimulus of interstitial flow.[82](#page-8-0) The interstitial flow can promote the expression of matrix metalloproteinase-2 protein to enhance the vasculogenic capacity of endothelial cells. Based on these inspiring works, we hypothesized that the perfusable patterned vascular models could be remodeled *in vitro* by delivering the patterned ECs with interstitial flow stimulation.

As a control, a group of patterned HUVECs and randomseeded HUVECs were cultured in the static culture conditions ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acsbiomaterials.3c00925/suppl_file/ab3c00925_si_001.pdf) S2). Although HUVECs could also self-assemble into vessel tubes in both groups, these blood vessels are essentially thin and nonperfused. For the experiment group, the patterned HUVECs were applied with hydraulic pressure by loading 50 *μ*L of medium into a 200 *μ*L pipet tip to induce interstitial flow. The patterned ECs began to interconnect in 24 h [\(Figure](#page-2-0) [2](#page-2-0)D). The ECs in the lumen not involved in vascularization were washed away in 48 h ([Figure](#page-2-0) 2Diii). Parts of the ECs migrated to the chamber wall, along which the ECs grew into the horizontal vessel tube to connect all of the vertical parallel patterned vessel tubes ([Figure](#page-2-0) 2E). After 48 h in an *in vitro* culture, a vascular network was formed, maintaining the shape of the previous acoustic patterning [\(Figure](#page-2-0) 2Ei). The vessel perfusability was demonstrated by loading the 10 *μ*m red fluorescent beads into the vessel tube [\(Figure](#page-2-0) 2Div). From the cytoskeleton characterization, it can be clearly seen that the blood vessels formed under hydraulic pressure stimuli were much wider than the static cultured blood vessels 83 ([Figures](#page-2-0) [2](#page-2-0)Eiii,iv and [S4](https://pubs.acs.org/doi/suppl/10.1021/acsbiomaterials.3c00925/suppl_file/ab3c00925_si_001.pdf)). To verify the HUVEC identity, the patterned vessel tubes were stained with red fluorescence conjugated CD31 antibody ([Figure](#page-2-0) 2F).^{[84](#page-8-0)}

Vascular Barrier Function Test of the Vessel Tube with/without the Supporting Fibroblasts. In addition to substance transportation, another important function of blood vessels is lateral permeability, which enables the exchange of substances with surrounding tissue, known as vascular barrier function. ^{85,[86](#page-8-0)} To evaluate the vascular barrier function in different scenarios, the monocultured vessel was set as the control and the fibroblast-supported vessel was set as the experiment group. 87 First, the suspended fibroblasts were

mixed into the HUVEC suspension and went through the acoustofluidic engineering process ([Figure](#page-3-0) 3A). After 2 days of culture, HUVECs could still interconnect and assemble into the straight vessel tubes while the fibroblasts were located on the outer wall of the vessel tube ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acsbiomaterials.3c00925/suppl_file/ab3c00925_si_001.pdf) S3A). [Figure](#page-3-0) 3B shows the confocal scanning of the fibroblast-supported vessel structure. The fibroblasts were labeled with red fluorescence conjugated α -smooth muscle actin antibody.⁸⁸

Then, the vascular barrier function was quantified by visualizing the diffusion of 70 kDa FITC-dextran solute.⁸⁹ The dextran solution was perfused into the parallel patterned vessel tubes through the anastomosis zone [\(Figure](#page-2-0) 2Eii) and permeated into the surrounding matrix. The monocultured vessel was leakier compared with the fibroblast-supported vessel [\(Figure](#page-3-0) 3C). The lateral diffusion rate of dextran in the monocultured vessel was almost twice that of the fibroblastsupported vessel [\(Figure](#page-3-0) 3D). For potential interpretation of the interaction between the solute and vascular cell membrane, an *in silico* atomistic model was proposed to visualize how the solute crossed the endothelial cell membrane ([Figure](#page-3-0) 4). As shown in [Figure](#page-3-0) 4Ai−iii, the dextran particles were allowed to diffuse through the membranes over time. The lipid bilayer membrane representative of HUVECs and fibroblasts is modeled by using two distinct membrane layers, with each layer consisting of three beads ([Figure](#page-3-0) 4Biii). The diffusion rate depends on the membrane permeability, which was derived from the optimized area per lipid ([Figure](#page-3-0) 4Bi,ii). For both membrane types, pure vessel and fibroblast-supported vessel, the diffusion rates obtained from our simulations closely mirrored those derived from actual experimental observations. To closely emulate the experimentally observed diffusion rates of membrane permeability, the area per lipid in the membrane was optimized by adjusting the Lennard-Jones parameters. Despite model simplifications like a uniform lipid bilayer representation and coarse-grained abstraction of lipid details, the model accurately captured the membrane permeability. Given this validation, our model holds promise for predicting permeability in other solute−membrane combinations.

Vascular Structure Influence Compound Transport in the Vessel-Associated Matrix. In addition to demonstrating that surrounding stromal cells can affect blood vessels, it was further shown that the vessel structure can also affect cells in the surrounding environment. Here, a functional assay was designed to show how vascular structure affects compound transport and influences neural activity. Induced pluripotent stem cell (iPSC)-derived neural cells were utilized, which express glutamate receptors^{[48](#page-7-0)} [\(Figure](#page-4-0) 5). As a control, the iPSC-derived neural cells were resuspended in the pure fibrinogen gel in a microfluidic chamber ([Figure](#page-4-0) 5Ai). For the experimental group, the neural cells were cocultured with the patterned vessel network [\(Figure](#page-4-0) 5Aii). Glutamate is one

of the major excitatory neurotransmitters in the mammalian central nervous system.^{[91](#page-8-0)} For the pure hydrogel matrix, a solution containing glutamate was loaded into the microfluidic chamber through one inject port. The compound travels through the matrix to reach the suspended cells by passive diffusion.^{[92](#page-8-0)} For the vessel-associated matrix, the compound was delivered through a patterned vessel network channel. After 10 min of treatment, the samples were washed to remove compound solution. After 20 min, the immune-staining for c-Fos was performed. The c-Fos gene expression can be activated by a wide range of stimuli and is a reliable marker of neural activity.^{[93](#page-8-0)} Its transcription was in rapid manner.⁹⁴ In the group in which the compound was delivered by blood vessels, the level of c-Fos expression in nerve cells was almost double that of the passive diffusion group ([Figure](#page-4-0) 5C). In a pure matrix without blood vessels, the substances are transported by passive diffusion, implying slow transport rates, limited transport distances, and spatial substance gradients. In a matrix with blood vessel networks, substances are transported directly in vessel tubes, which serve as highways, and reach the bulk of the matrix more quickly. $\frac{5}{5}$

■ **CONCLUSION**

The reported acoustofluidic engineering of vessel-on-a-chip not only inherited the advantages of previous acoustophoretic publications^{[81,96](#page-8-0)} but also incorporated technical points from the literature about hydraulic pressure activating vessel formation[.97](#page-8-0),[98](#page-8-0) To demonstrate the function of the acoustofluidic engineered vascular structure, the perfusability and permeability of the vessel-on-a-chip was verified. Further, a molecular dynamic computational model was proposed to illustrate how the compound crosses the vascular lipid layer. Lastly, a vessel−neural cell coculture system was established to demonstrate that the vascular structure played an important role in the compound delivery process. In general, we reported an acoustofluidic methodology to engineer an *in vitro* vesselon-a-chip model. It is believed that the proposed method can contribute to tissue engineering and regenerative medicine application. In the future, this method has the opportunity to further combine different patterning modes of the sound field ([Figure](https://pubs.acs.org/doi/suppl/10.1021/acsbiomaterials.3c00925/suppl_file/ab3c00925_si_001.pdf) S5A) to create functional vascular tissues of the specific shapes.^{[99,100](#page-8-0)}
